

Splay Tree

The Splay Tree is constructed using the elements $\{100, 50, 200, 40, 30, 20\}$. During the search operation for 20, the node 20 lies in a left-left configuration with its ancestors. Therefore, Zig-Zig rotations are performed. Two consecutive right rotations are applied at each level, moving 20 upward toward the root. After the required Zig-Zig rotations, 20 becomes the root of the Splay Tree. This demonstrates the self-adjusting property of Splay Trees, where frequently accessed elements are moved closer to the root for faster future access.
